This file is maintained by the \LaTeX{} Project team. Bug reports can be opened (category latex) at https://latex-project.org/bugs.html.

Abstract

This file implements an \ifthenelse command for \LaTeX{} 2\varepsilon. The algorithm used is compatible with that used in the \LaTeX{} 2.09 ifthen style option. It has been recoded, making the resulting definitions somewhat more compact and efficient.

1 Introduction

\ifthenelse\{\langle test \rangle\}\{\langle then clause \rangle\}\{\langle else clause \rangle\}

Evaluates $\langle test \rangle$ as a boolean function, and then executes either $\langle then clause \rangle$ or $\langle else clause \rangle$.

$\langle test \rangle$ is a boolean expression using the infix connectives, \texttt{\&}, \texttt{\|}, the unary \texttt{\neg} and parentheses \texttt{(} \texttt{)}. As an alternative notation \texttt{\&\&}, \texttt{\|\|} and \texttt{\neg\neg} can be used. This is safer since it can’t be misinterpreted when appearing inside a \TeX-conditional in which \texttt{\|} has a different meaning.

The atomic propositions are:

$\langle number \rangle < \langle number \rangle$
$\langle number \rangle = \langle number \rangle$
$\langle number \rangle > \langle number \rangle$
\texttt{\isodd}\{\langle number \rangle\}
\texttt{\isundefined}\{\langle command name \rangle\}
\texttt{\equal}\{\langle string \rangle\}\{\langle string \rangle\}
\texttt{\lengthtest}\{\langle dimen \rangle<\langle dimen \rangle\}
\texttt{\lengthtest}\{\langle dimen \rangle=\langle dimen \rangle\}
\texttt{\lengthtest}\{\langle dimen \rangle>\langle dimen \rangle\}
\texttt{\boolean}\{\langle name \rangle\}

The $\langle string \rangle$s tested by \texttt{\equal} may be any sequence of commands that expand to a list of tokens. If these expansions are equal, then the proposition is true.

\texttt{\isodd} is true if the $\langle number \rangle$ is odd, and false otherwise (even if the argument is not a number).

*This file has version number v1.1c, last revised 2020/11/24.
\isundefined{\cmd} is true if \cmd is not defined.
\boolean{xyz} returns the truth value contained in the primitive \TeX \if. \ifxyz. This is usually used with boolean flags created with \newboolean and \provideboolean described below. It can also be used with the names of \newif created tokens, and primitive \TeX \if constructs, for example \boolean{true} \iftrue, \boolean{mmode} \ifmmode etc.

The commands:
\newboolean{⟨name⟩} and \provideboolean{⟨name⟩} are provided so the user can easily create new boolean flags. As for \newcommand, \newboolean generates an error if the command name is not new. \provideboolean silently does nothing in that case.

The boolean flags may be set with:
\setboolean{⟨name⟩}{⟨value⟩}
⟨value⟩ may be either \texttt{true} or \texttt{false} (any CaSe).

Note that there is no precedence between \and and \or. The proposition is evaluated in a left right manner. \not only applies to the immediately following proposition. (This is consistent with Lamport’s \texttt{ifthen.sty}.) In this style, though the test is ‘lazily’ evaluated, so for instance if the first proposition in an \or is true, the second one is skipped. (On the second pass—the first pass in an \edef expands clauses in all propositions.)

Apart from the addition of the extra atomic propositions \isodd, \boolean, \lengthtest and \isundefined, the only known incompatibility is that in this package the expression \not\not⟨P⟩ is equivalent to ⟨P⟩. However in the original style it was equivalent to \not⟨P⟩. This is intentional (bug fix:-).

The command \whiledo is also defined (copied directly from the \texttt{L\TeX2.09} definition).
\whiledo{⟨test⟩}{⟨while clause⟩}
With ⟨test⟩ as above, repeatedly executes ⟨while clause⟩ while the test remains true.

2 The Implementation

1 (*package)
\TE@throw In order to support the syntax of \texttt{ifthen.sty}, which allows access to the primitive \TeX syntax for a numeric test, rather than a \{\} delimited argument form, it is most convenient to work ‘within’ an \ifnum. \ift@throw ‘throws’ you out of the current \ifnum so that you can (eg) start an \ifdim for the length tests.
2 \def\TE@throw{\if\ifdim\expandafter\csname if\endcsname#1\endcsname\fi}
\boolean A non-standard extension to \texttt{ifthen}, supporting boolean was previously available, this is a simpler implementation.
3 \def\boolean#1#2{%
4 \TE@throw\expandafter\noexpand\csname if#1\endcsname#2}
\TE@length Testing lengths. \#1 is the test. The extra argument gobbles spaces.
5 \def\TE@length#1#2{\TE@throw\noexpand\ifdim#1#2}
\TE@odd Testing odd/even. This is true if \#1 is an odd number, and false otherwise (even \TE@odd if \#1 is not a number at all).
It is hard to make this completely reliable. Here I have erred on the side of safety. This should not generate a TeX error if given any robust commands as its argument. However it returns true on any argument that starts with an odd number 11xx which is bad, and it can not deal with TeX’s count registers, although LATEX counters work (via \value).

\def\TE@odd#1#2{% 
  \TE@throw\noexpand\TE@@odd#1\noexpand\@nil\noexpand\ifodd\count@#2
} \TE@@odd is not expanded on the first pass.

\def\TE@@odd#1#2\@nil{% 
  \@defaultunits \count0\if-#1-0\else0\expandafter#1\fi#2\relax\@nnil
}\TE@repl \TE@repl replaces the single token #1 by #2. (Not within \{} groups.) It is used to replace \or by \TE@or without the need to redefine \or. Earlier versions just \let\or\TE@or but this has a bad effect on the expansion of commands which use the primitive \or internally, eg \alph, and so caused surprising results if these commands were used inside \equal.

\def\TE@repl#1#2{% 
  \long\def\@tempc##1#1##2{% 
    \def\@tempa{##2}\def\@tempb{\@tempc} \ifx\@tempa\@tempb
    \toks@\expandafter{\the\toks@##1} \expandafter\@gobble
    \else \toks@\expandafter{\the\toks@##1#2} \expandafter\@tempc \the\toks@#1\@tempc\fi
  } \expandafter\@tempc\the\toks@#1\@tempc
}\ifthenelse The remaining macros in this file are derived from the ones in ifthen.sty but recoded and simplified. The main simplification is that the original style (and the \boolean extensions) expressed logical values always in terms of \ifnum. As \if is ‘untyped’ this is not necessary, so for example the length tests can return values via \ifdim, the trailing \fi will not complain, even though it was ‘expecting’ an \ifnum. Also the system of passing information via macros expanding to T or F has been completely replaced by a simpler system using \iftrue, which furthermore allows lazy evaluation on the second pass.

\long\def\ifthenelse#1{% 
  \toks@{#1} \TE@repl\OR\TE@or \TE@repl\AND\TE@and \TE@repl\NOT\TE@neg
} Support alternate names for the boolean operators (strictly speaking only \OR would be necessary).

\TE@repl\OR\TE@or \TE@repl\AND\TE@and \TE@repl\NOT\TE@neg

3
The original ifthen.sty processed everything inside a box assignment, to catch any extra spaces before they appeared in the output. Instead I have added extra arguments to the commands so they each remove any following space.

Set up the user level names `not` etc.

For the first pass, in a group, make various tokens non-expandable.

It is unfortunate that in order to remain compatible with ifthen syntax, it is necessary to have a two pass system. The first pass inside an `edef` 'exposes' the \if...\fi tokens, so the correct clauses may be skipped on the second pass. This means that the whole `ifthenelse` command does not work by expansion, and so possibly has only limited usefulness for macro code writers. The main problem with the ifthen: syntax is that (unique for \LaTeX) it does not uses a brace delimited argument form, and exposes the primitive \TeX syntax for \langle number\rangle. Pretty much the only way of parsing 1 > 2 \or 2 < 1 is to actually evaluate the primitive `ifnum`. A syntax such as:
\or\numtest{1<2}\{\lengthtest{1pt<1in}}

\begin{verbatim}
\begingroup
 \let\@tempa\relax \let\@tempb\relax
 \xdef\@gtempa{\expandafter\TE@eval\the\toks\TE@endeval}
\endgroup
\end{verbatim}

Now outside the group, execute `@gtempa` which causes all the `ifs` etc., to be evaluated, the final truth value is contained in the `newif` token `ifTE@val`. Finally this is tested and either the first or second following argument is chosen accordingly.

\begin{verbatim}
@gtempa
 \expandafter\endgroup\ifTE@val
   \expandafter\@firstoftwo
 \else
   \expandafter\@secondoftwo
 \fi
\end{verbatim}

`\TE@eval` Initialise a term. (Expanded on the first pass).

`\ifTE@val` Two `newifs` the first holds the current truth value of the expression. The second is a temporary flag which is true if we need to negate the current proposition.

`\ifTE@negate`
Finalize a term. (Expanded on the first pass.)
\def\TE@endeval{%
\noexpand\TE@setvaltrue\noexpand
\else
\noexpand\TE@setvalfalse\noexpand
\fi
\noexpand\TE@negatetrue\noexpand
\fi}

\def\TE@setvaltrue{%
\ifTE@negate\TE@valfalse\else\TE@valtrue\fi
}
\def\TE@setvalfalse{
\let\ifTE@val\ifTE@negate

\def\TE@or{
\TE@endeval\noexpand\ifTE@val
\noexpand\else
\noexpand\ifnum}

\def\TE@and{
\TE@endeval\noexpand\ifTE@val
\noexpand\ifnum}

\def\TE@neg{
\TE@throw\noexpand\TE@negswitch
\noexpand\ifnum}

\def\TE@negswitch{
\ifTE@negate\TE@negatefalse\else\TE@negatetrue\fi

\def\TE@lparen#1{\TE@throw\begingroup\TE@eval#1}
\def\TE@rparen#1{\TE@endeval
\noexpand\expandafter\endgroup
\noexpand\ifTE@val#1}
